

# Writing UDP-based Servers and Clients

Chris Brown

# In This Module ...

Client and server-side operations using UDP

UDP sockets API

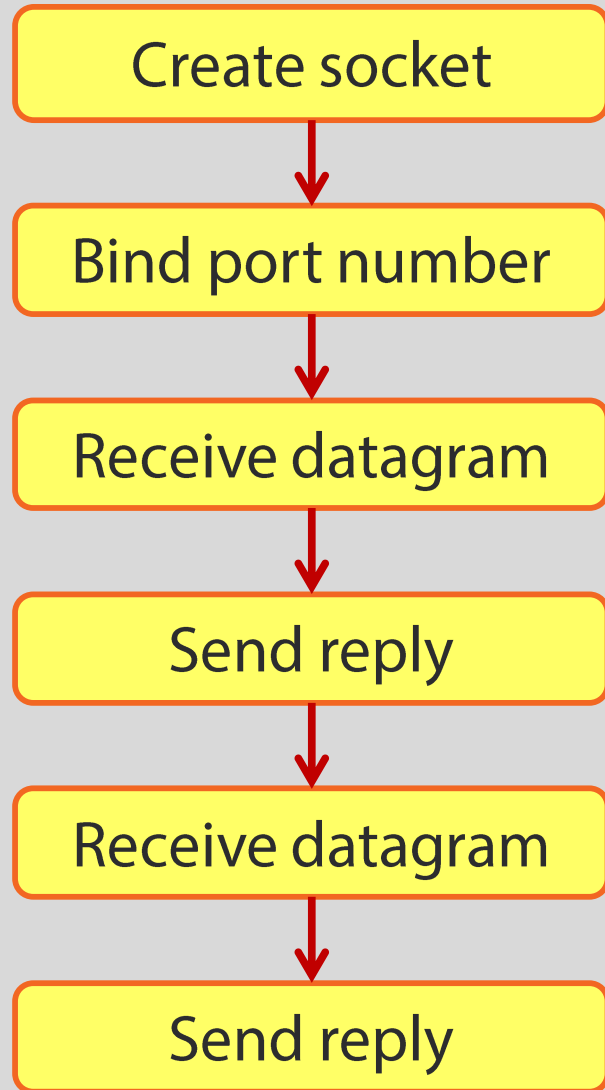

A binary application protocol (TFTP)

Demonstration:  
rcat – a TFTP client

Broadcasting with UDP

Demonstration:  
A UDP broadcast application

# Server

# Client 1

# Client 2

# The Bucket Analogy

# The Postbox Analogy

Each message is individually addressed

~~connect()~~

~~accept()~~

~~listen()~~

```
struct sockaddr_in{..}
```

# Coping with Unreliability

UDP is "unreliable"

- packets may get dropped
- or may be mis-ordered

Is the underlying network  
"reliable enough"?

?

Can we tolerate occasional dropped packets?  
— Catastrophic failure of application?  
— Gradual degradation of performance?

?

Handle acknowledgements, timeouts and  
re-transmissions within the application protocol

?

# Creating a Socket

Transport type:  
SOCK\_STREAM  
SOCK\_DGRAM

```
sock = socket(domain, type, protocol)
```

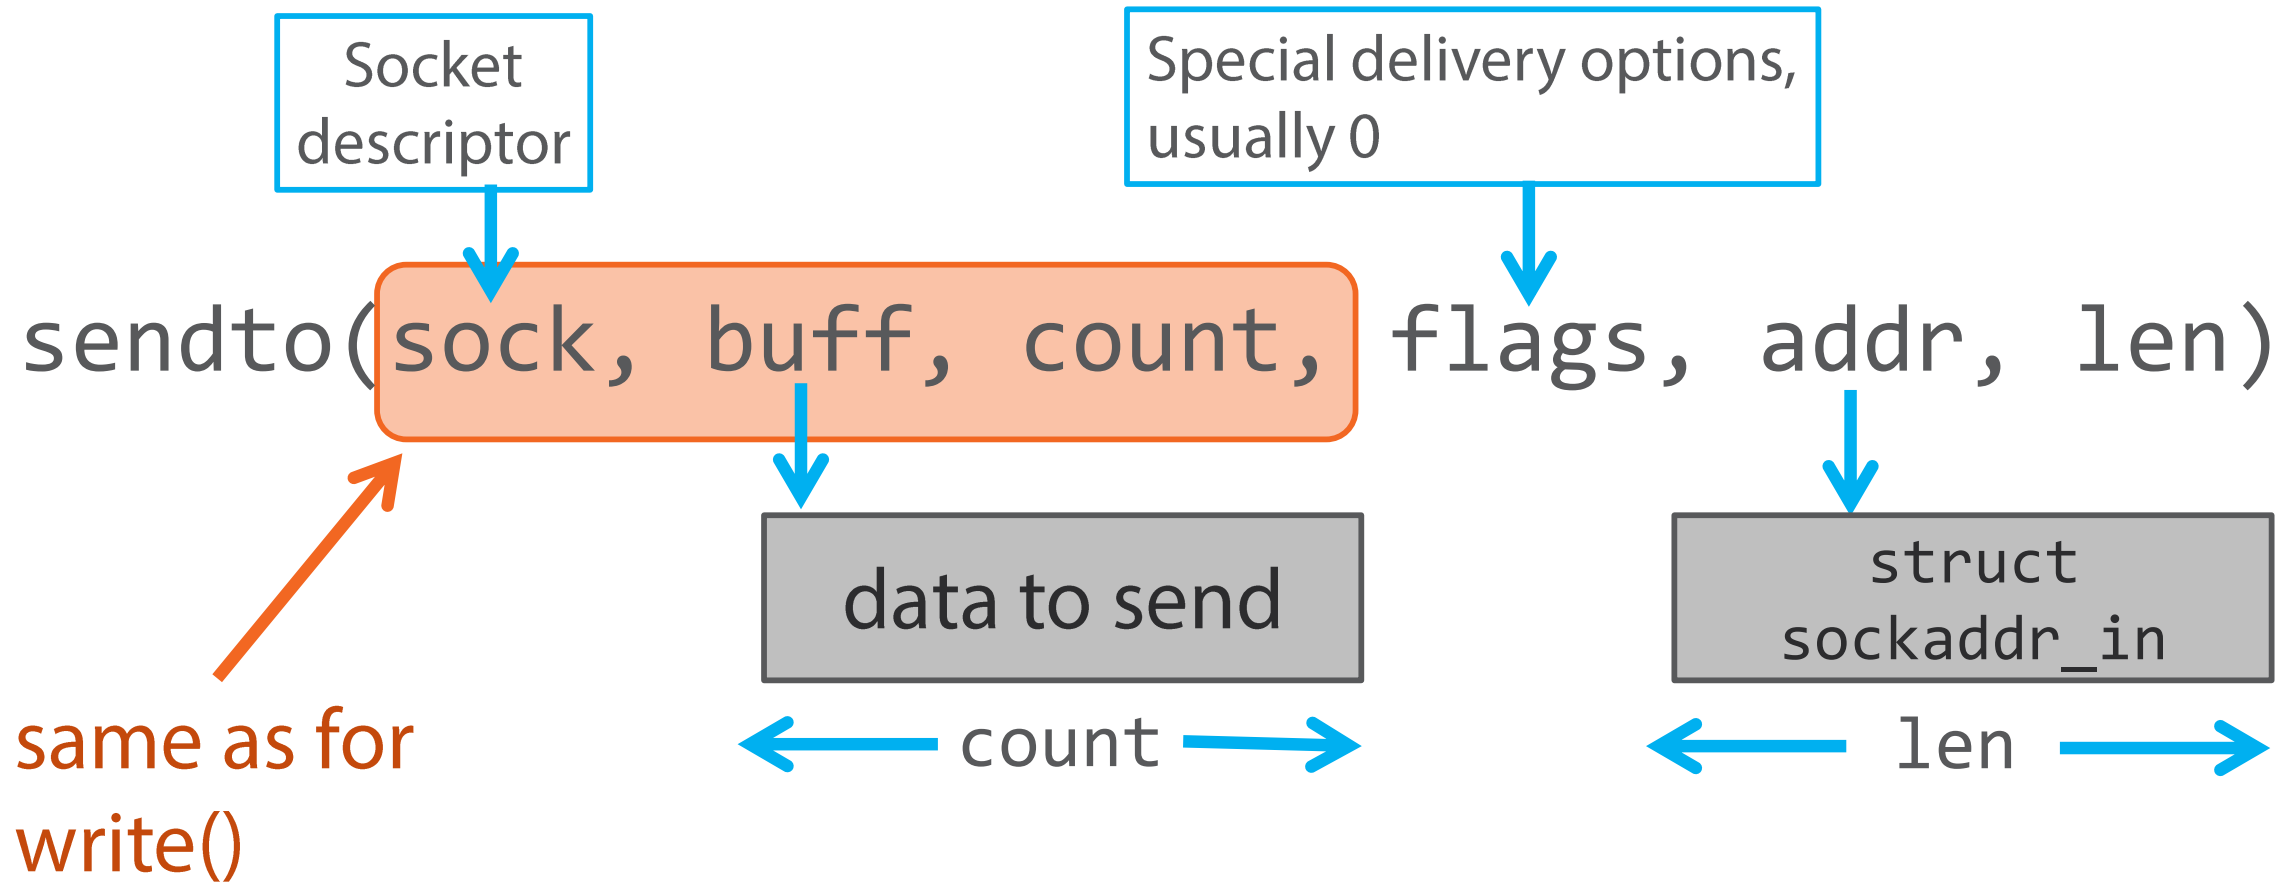

Returns an integer  
socket descriptor  
or -1 on error

The address family. One of:  
AF\_UNIX  
AF\_INET  
AF\_INET6

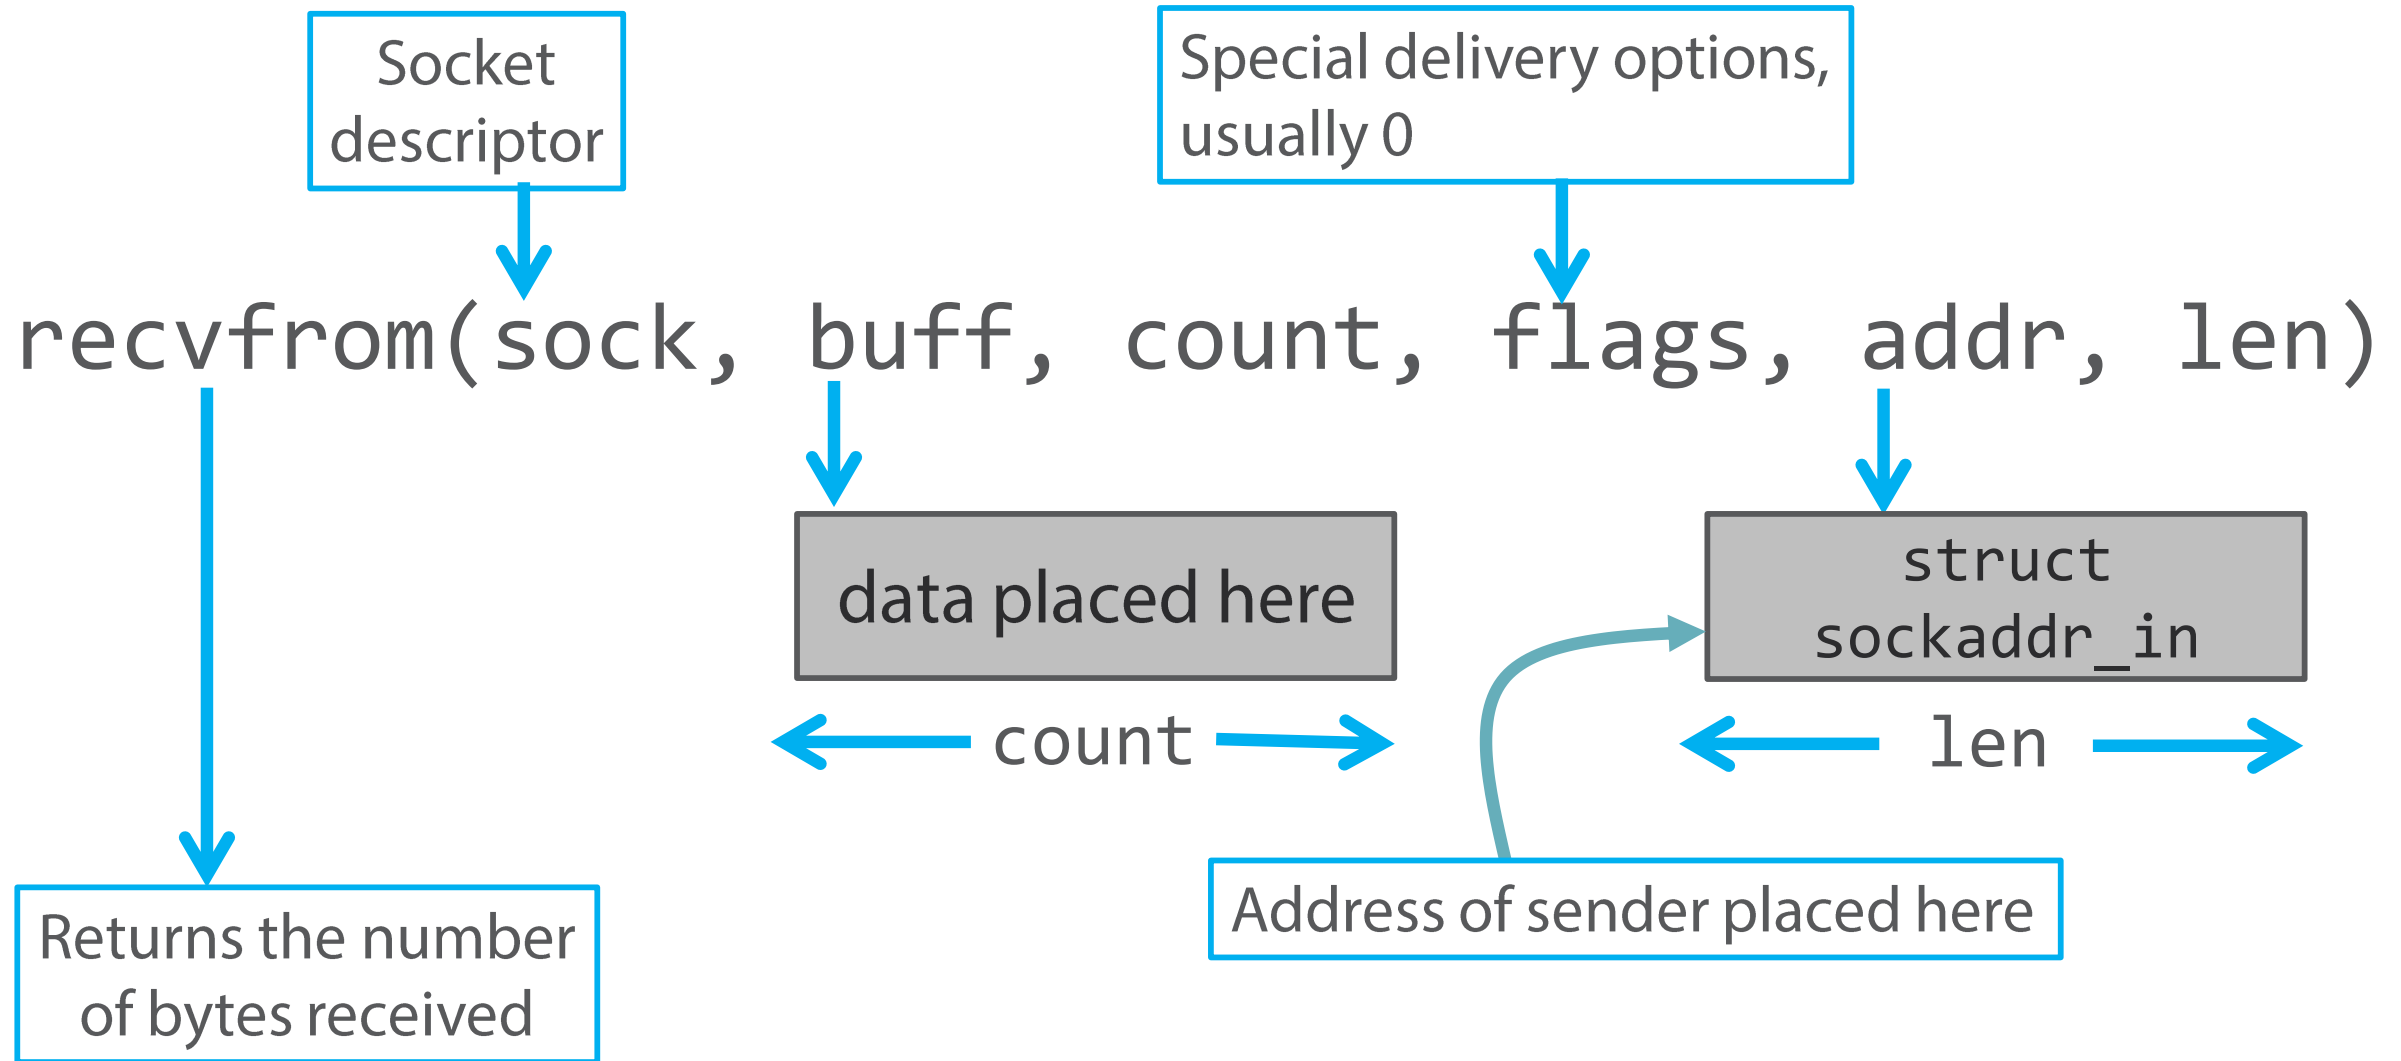

Usually 0, system  
selects protocol  
based on domain  
and type

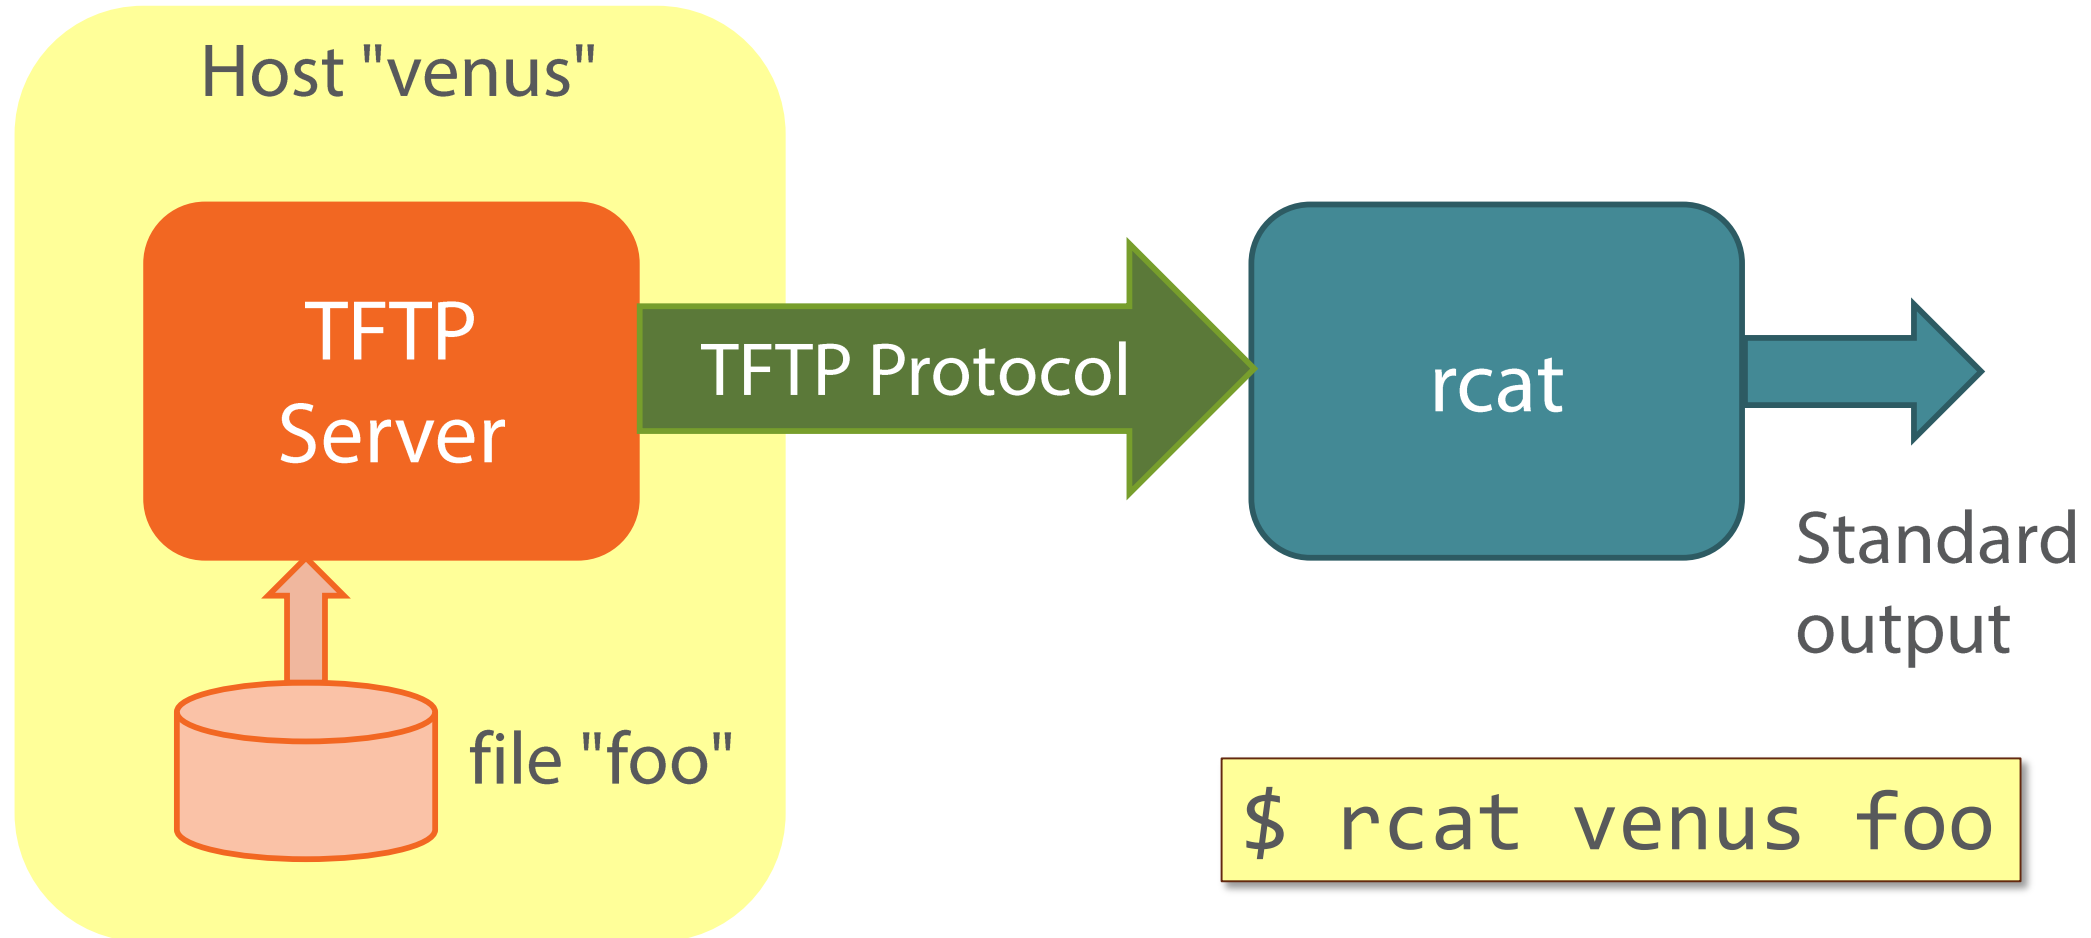

# Sending a Datagram

# Receiving a Datagram

# Our UDP Demonstration Client

# Protocols

*protocol – a set of rules governing the exchange or transmission of data between devices*

Text-based:

- Based on text strings (human readable)
- HTTP, Telnet, SMTP, ...

Binary:

- Based on data structures (machine-readable)
- IP, TCP, UDP, TFTP, ...

# Introducing TFTP

- Trivial File Transfer Protocol
- Simple design
  - Small code footprint
- Useful to download kernel image, etc. to small systems
- No authentication or access control
  - Server often confined to `/tftpboot` directory
- Consult RFC1350 for the full story

# TFTP Packet Formats

IP Header	UDP Header	Opcode 1 = RRQ	File name	0	Mode	0
-----------	------------	-------------------	-----------	---	------	---

20 bytes

8 bytes

2 bytes

N bytes

N bytes

Opcode 3 = Data	Block number	data
--------------------	--------------	------

2 bytes

2 bytes

0 - 512 bytes

Opcode 4 = ACK	Block number
-------------------	--------------

2 bytes

2 bytes

Opcode 5 = error	Error number	Error message	0
---------------------	--------------	---------------	---

# TFTP Packet Formats

← IP Datagram →

← UDP Datagram →

← TFTP Message →

# TFTP Operation

# TFTP Operation

# TFTP Operation

# Demonstration

rcat – a TFTP client

UDP Packet Trace

# UDP Broadcasting

UDP supports  
broadcasting

Datagram sent  
using IP host ID of  
"all ones"

All recipients must  
listen on same port

Packet size limited  
by MTU of  
underlying network

Does not work  
through routers

# Broadcasting – Core Code

```
int sock, yes = TRUE;
struct sockaddr_in bcast;
char data[100];

sock = socket(AF_INET, SOCK_DGRAM, 0);
setsockopt(sock, SOL_SOCKET, SO_BROADCAST, &yes, sizeof yes);

bcast.sin_family = AF_INET;
bcast.sin_addr.s_addr = 0xffffffff;
bcast.sin_port = htons(MY_PORT);

sendto(sock, &data, sizeof data, 0, &bcast, sizeof bcast);
```

# A Distributed Update Service

Multiple  
Participants

Each generates  
status information  
periodically

Each needs to  
receive status  
updates from all  
the others

Each displays the  
overall status

# Fully Connected Model

$$N * (N - 1)$$

# Intermediate Delivery Agent

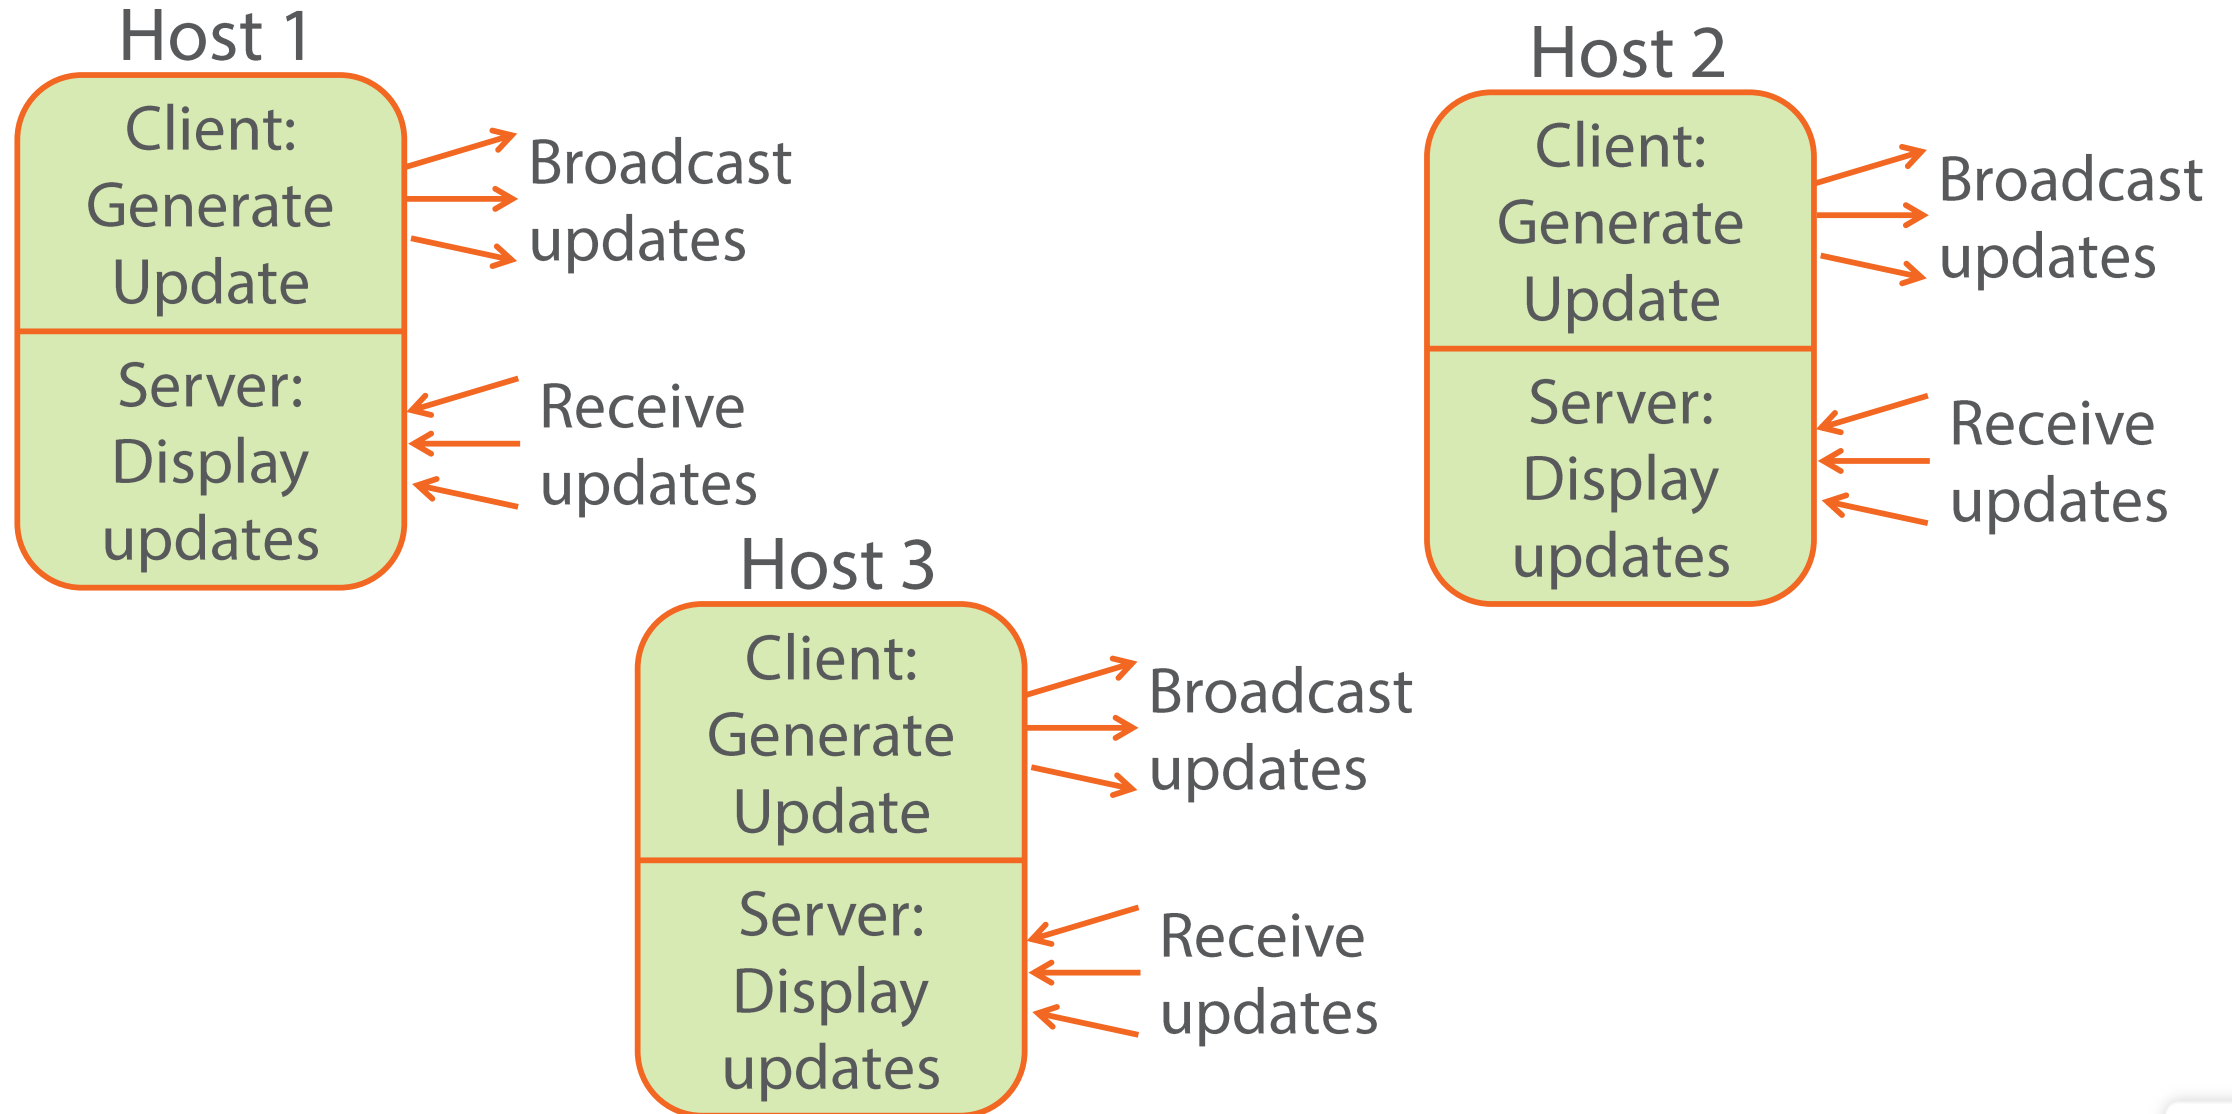

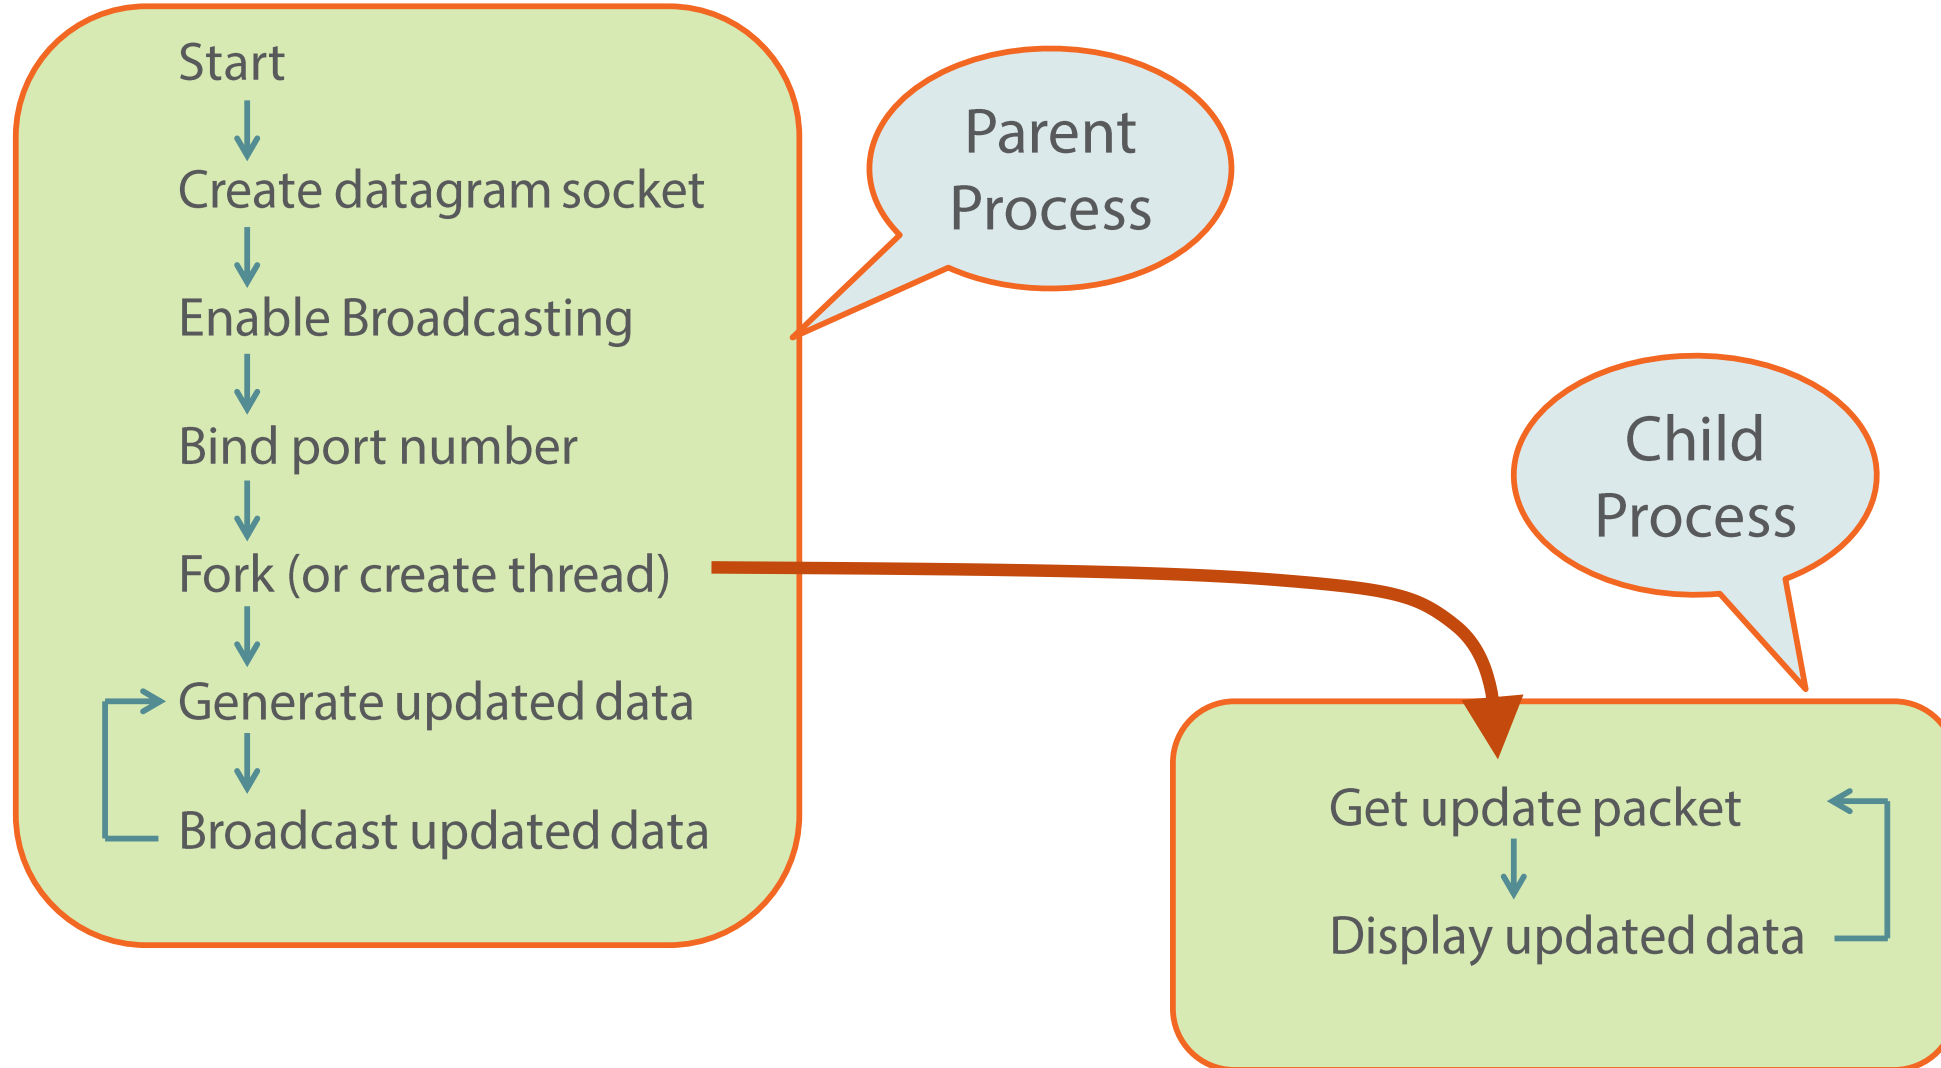

# Broadcast Model

# Peer-to-Peer Operation

# Program Structure

# Demonstration:

## A Distributed Update Service

# Moving Forward ...

In this module:

- UDP sequence of operations

- UDP sockets API

- Text and binary protocols

- The rcat client

- UDP broadcasting

- Distributed update service

Coming up in the next module:

- Concurrent servers and clients
